## C Macro Definitions for the MC68HC11F1

By John Bodnar  
Austin, Texas

### Introduction

---

With more microcontroller users moving to high level languages like C, macro definition files like the one outlined in this document can speed software development efforts. The file reproduced in the following pages is available on the Freeware Data System. Download and unzip the hc11f1h.zip file from the MCU11 directory.

The hc11f1h.zip file includes an ASCII text copy of this documentation and the actual hc11f1.h text file. The hc11f1.h file, and others like it, use Motorola's designated register and bit names for each device described. Any user already familiar with MC68HC11 assembly language and architecture (a requirement even for those who think they will only program in C), will readily be able to make use of this file.

### Conventions

---

The contents of the actual file will be designated with the Courier typeface while commentary will appear in the Helvetica typeface used in this paragraph.

Thus these lines appear in the hc11f1.h file:

```
/* MOTOROLA INC.  
  
*  
  
* FILENAME: hc11f1.h  
  
*  
  
* DESCRIPTION: Register and bit macro definitions for the  
* MC68HC11F1 microcontroller.  
  
*  
  
* CREATED: 11/18/93  
  
*  
  
* NOTE: Your comments, suggestions, and corrections are requested  
* and greatly appreciated.  
  
*/
```

First references to key terms appear in bold type, and C keywords and expressions appear in italics.

## Concepts, Development, and Usage

---

In C, we can make just about anything an lvalue, that is, something that appears to the left of the equal sign in an assignment expression. We can even use a number as an lvalue. In particular, we would like to use register addresses as lvalues. To do this, we must cast the lvalue as a pointer to a particular data type.

For example

```
(unsigned char *) 0x1000
```

would be an lvalue that points to an unsigned character (an 8 bit unsigned value) at memory location 0x1000 (0x1000 for those used to assembly language). In this particular form, however, we cannot yet assign a value to the memory location. To do this, we must de-reference the pointer.

De-referencing a pointer specifies the value that is pointed to and not the pointer itself. So, to assign the value 0xFF to memory location 0x1000, we would use this C assignment expression:

```
*(unsigned char *) 0x1000 = 0xFF
```

Likewise, to assign the contents of memory location 0x1000 to the variable A, use the following assignment:

```
A = *(unsigned char *) 0x1000
```

This is all that is really necessary to manipulate the memory mapped registers of the MC68HC11. Unfortunately, `*(unsigned char *) 0x1000` is not particularly indicative of the function memory location 0x1000 performs (PORT A on most MC68HC11 devices). The extra typing required to use this memory location can also be a source of minor, but unnecessary compilation errors. A better idea is to use this line (remember, lines appearing in the `hc11f1.h` file appear in the Courier typeface):

```
#define REGISTER unsigned char
```

Thus to access memory location 0x1000, we can now type

```
A = *(REGISTER *) 0x1000
```

This is an improvement, but it would be even better if we could define a register as PORTA or DDRC as we do when programming in assembly. Thus this line

```
#define SOMEDEVICE *(REGISTER *)0x1000
```

will allow us to address 0x1000 in a very convenient fashion. For example, we can now type

```
SOMEDEVICE = 0xFF
```

to assign 0xFF to memory location 0x1000, and we can also type

```
A = SOMEDEVICE
```

to assign the contents of 0x1000 to the variable A.

The MC68HC11 has an INIT register which is used to remap internal RAM and registers to the beginning of any 4-K page of memory. Some applications may require register remapping, so it would be convenient if we could make a simple change to the macro definition file to account for this. The following line (part of hc11f1.h) allows us to do this:

```
#define REG_BASE 0x1000
```

We can thus use the following macro definition to handle register relocation:

```
#define SOMEDEVICE *(REGISTER *)(REG_BASE + 0x00)
```

If we leave REG\_BASE as 0x1000, then pointers to the MC68HC11's peripheral registers will be addressed at 0x1000 in our source code. If we decide to remap the registers to 0x4000, we can simply replace 0x1000 in the #define REG\_BASE macro with 0x4000.

**NOTE:** *This does not actually modify the MC68HC11's INIT register. This must be done by modifying your C compiler's run-time start up code. Refer to your compiler's documentation before making any such changes.*

Before proceeding with the rest of the hc11f1.h file, we need to understand the use of C's volatile keyword. By specifying a variable as volatile, we tell the C compiler not to optimize expressions using that variable.

```
#define PORT *(REGISTER *)(REG_BASE + 0xA0)
void main()
{
    PORT = 0x00;
    etc... /* PORT is not used until while(PORT) */
    while (PORT)
    {
        etc...
    }
}
```

In this program fragment, we immediately initialize PORT to 0x00, but we will not reference it again until the while (PORT) expression. Unless PORT were to somehow change, while (PORT) would be false, and code in the braces immediately following would not execute.

Some C compilers may view this as unnecessary if PORT never changes, and it is possible these lines could be optimized out of the resulting object code.

On the MC68HC11, PORT may point to a bi-directional I/O port whose inputs may change during program execution, thus the while (PORT) expression could actually be true when it is executed. As a precaution, designate the PORT pointer as volatile so the optimizer will not attempt to remove any questionable references to it. Thus change the #define macro to

```
#define PORT *(volatile REGISTER*)(REG_BASE + 0xA0)
```

By doing this, references to PORT will not be optimized. Several registers on the MC68HC11 can change without the intervention of user code.

These registers include port data registers (PORTC), peripheral status registers (SPSR), peripheral data registers (SCDR, ADR1), flag registers

(TFLG1), and timer registers (TCNT, TIC3).

We could use the volatile keyword with every register macro definition to simplify matters, but this runs counter to good code documentation. By specifying only those registers which require it as volatile, the resulting code will be better documented. Only registers which can receive data externally or be changed by the processor without user intervention will be declared volatile. Write only registers will be easily recognized because they will lack the volatile declaration.

These macro definitions are used for the registers on the MC68HC11F1 device:

```
#define PORTA (*(volatile REGISTER*)(REG_BASE + 0x00))
#define DDRA *(REGISTER*)(REG_BASE + 0x01))
#define PORTG (*(volatile REGISTER*)(REG_BASE + 0x02))
#define DDRG *(REGISTER*)(REG_BASE + 0x03))
#define PORTB *(REGISTER*)(REG_BASE + 0x04))
#define PORTF *(REGISTER*)(REG_BASE + 0x05))
#define PORTC (*(volatile REGISTER*)(REG_BASE + 0x06))
#define DDR *(REGISTER*)(REG_BASE + 0x07))
#define PORTD (*(volatile REGISTER*)(REG_BASE + 0x08))
#define DDRD *(REGISTER*)(REG_BASE + 0x09))
#define PORTE (*(volatile REGISTER*)(REG_BASE + 0x0A))
#define CFORC *(REGISTER*)(REG_BASE + 0x0B))
#define OC1M *(REGISTER*)(REG_BASE + 0x0C))
#define OC1D *(REGISTER*)(REG_BASE + 0x0D))
```

The following registers (TCNT, TICx, and TOCx) are declared as unsigned integers because they are 16 bit registers and should be accessed as such. It is much simpler and clearer to change, for example, the output compare 4 register by using

TOC4 = 0x4000, TOC4 = TCNT + 0x20FF, or TOC4 += 0x3200.

```
#define TCNT (*(volatile unsigned int*)(REG_BASE + 0x0E))
#define TIC1 (*(volatile unsigned int*)(REG_BASE + 0x10))
#define TIC2 (*(volatile unsigned int*)(REG_BASE + 0x12))
#define TIC3 (*(volatile unsigned int*)(REG_BASE + 0x14))
#define TOC1 *(unsigned int*)(REG_BASE + 0x16))
#define TOC2 *(unsigned int*)(REG_BASE + 0x18))
#define TOC3 *(unsigned int*)(REG_BASE + 0x1A))
#define TOC4 *(unsigned int*)(REG_BASE + 0x1C))
```

```
#define TI4O5 (*(volatile unsigned int*)(REG_BASE + 0x1E))
#define TCTL1 *(REGISTER*)(REG_BASE + 0x20)
#define TCTL2 *(REGISTER*)(REG_BASE + 0x21)
#define TMSK1 *(REGISTER*)(REG_BASE + 0x22)
#define TFLG1 *(volatile REGISTER*)(REG_BASE + 0x23)
#define TMSK2 *(REGISTER*)(REG_BASE + 0x24)
#define TFLG2 *(volatile REGISTER*)(REG_BASE + 0x25)
#define PACTL *(REGISTER*)(REG_BASE + 0x26)
#define PACNT *(volatile REGISTER*)(REG_BASE + 0x27)
#define SPCR *(REGISTER*)(REG_BASE + 0x28)
#define SPSR *(volatile REGISTER*)(REG_BASE + 0x29)
#define SPDR *(volatile REGISTER*)(REG_BASE + 0x2A)
#define BAUD *(REGISTER*)(REG_BASE + 0x2B)
```

SCCR1 is declared volatile because it has the R8 bit, the ninth data bit received when SCI mode 1 is used. The remaining bits in this register are write only.

```
#define SCCR1 *(volatile REGISTER*)(REG_BASE + 0x2C)
#define SCCR2 *(REGISTER*)(REG_BASE + 0x2D)
#define SCSR *(volatile REGISTER*)(REG_BASE + 0x2E)
#define SCDR *(volatile REGISTER*)(REG_BASE + 0x2F)
```

ADCTL is declared volatile because bit 7, the conversion complete flag (CCF), is changed without user intervention. The remaining bits in this register are write only.

```
#define ADCTL *(volatile REGISTER*)(REG_BASE + 0x30)
#define ADR1 *(volatile REGISTER*)(REG_BASE + 0x31)
#define ADR2 *(volatile REGISTER*)(REG_BASE + 0x32)
#define ADR3 *(volatile REGISTER*)(REG_BASE + 0x33)
#define ADR4 *(volatile REGISTER*)(REG_BASE + 0x34)
#define BPROT *(REGISTER*)(REG_BASE + 0x35)
#define OPT2 *(REGISTER*)(REG_BASE + 0x38)
```

```
#define OPTION (*(REGISTER *)(REG_BASE + 0x39))
#define COPRST (*(REGISTER *)(REG_BASE + 0x3A))
#define PPROG  (*(REGISTER *)(REG_BASE + 0x3B))
#define HPRIO  (*(REGISTER *)(REG_BASE + 0x3C))
#define INIT   (*(REGISTER *)(REG_BASE + 0x3D))
#define TEST1  (*(REGISTER *)(REG_BASE + 0x3E))
#define CONFIG (*(REGISTER *)(REG_BASE + 0x3F))
#define CSSTRH (*(REGISTER *)(REG_BASE + 0x5C))
#define CSCTL  (*(REGISTER *)(REG_BASE + 0x5D))
#define CSGADR (*(REGISTER *)(REG_BASE + 0x5E))
#define CSGSIZ (*(REGISTER *)(REG_BASE + 0x5F))
```

C also allows declaration of individual bit fields as constants. This allows simple register bit assignments and comparisons. For instance

```
while (!(SPSR & SPIF))
```

can be used to halt program execution until the SPI status register SPIF bit has set. Likewise, use

```
SPCR = SPIE + SPE + MSTR + CPHA + SPR0
```

to configure the SPI for master operation with interrupts using clock phase 1 and a baud rate of E clock divided by 4. We can also use these constants to clear individual bit fields in the timer flag registers.

```
TFLG1 &= OC3F
```

This clears output compare flag 3 without affecting the other bits in the TFLG1 register.

A partial list of the macro definitions used for the register bit fields on the MC68HC11F1 device follows. For a complete list, see the file 3hc11f1h.zip2 on the Freeware Data System.

```
/* Bit names for general use */
```

```
#define bit7  0x80  
#define bit6  0x40  
#define bit5  0x20  
#define bit4  0x10  
#define bit3  0x08  
#define bit2  0x04  
#define bit1  0x02  
#define bit0  0x01
```

```
/* PORTA bit definitions 0x00 */
```

```
#define PA7   bit7  
#define PA6   bit6  
#define PA5   bit5  
#define PA4   bit4  
#define PA3   bit3  
#define PA2   bit2  
#define PA1   bit1  
#define PA0   bit0
```

```
.  
.  
.
```

```
/* CSGSIZ bit definitions 0x5F */
```

```
#define IO1AV  bit7  
#define IO2AV  bit6  
#define GNPOL  bit4  
#define GAVLD  bit3  
#define GSIZA  bit2  
#define GSIZB  bit1  
#define GSIZC  bit0
```

Motorola reserves the right to make changes without further notice to any products herein. Motorola makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Motorola assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters which may be provided in Motorola data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. Motorola does not convey any license under its patent rights nor the rights of others. Motorola products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Motorola product could create a situation where personal injury or death may occur. Should Buyer purchase or use Motorola products for any such unintended or unauthorized application, Buyer shall indemnify and hold Motorola and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Motorola was negligent regarding the design or manufacture of the part.
