## Mask Set Errata 4

# 68HC08AS20 8-Bit Microcontroller Unit

## INTRODUCTION

This mask set errata provides information pertaining to the SPI module applicable to these 68HC08AS20 MCU mask set devices:

- 0G39Y, 1G39Y, 2G39Y
- 0H94K

## MCU DEVICE MASK SET IDENTIFICATION

The mask set is identified by a 5-character code consisting of a version number, a letter, two numerical digits, and a letter, for example 0G39Y. Slight variations to the mask set identification code may result in an altered version number, for example 1G39Y.

## MCU DEVICE DATE CODES

Device markings indicate the week of manufacture and the mask set used. The data is coded as four numerical digits where the first two digits indicate the year and the last two digits indicate the work week. For instance, the date code "9115" indicates the 15th week of the year 1991.

## MCU DEVICE PART NUMBER PREFIXES

Some MCU samples and devices are marked with an SC or XC prefix. An SC prefix denotes special/custom device. An XC prefix denotes that the device is tested but is not fully characterized or qualified over the full range of normal manufacturing process variations. After full characterization and qualification, devices will be marked with the MC prefix.

When contacting a Motorola representative for assistance, please have the MCU device mask set and date code information available.

Specifications and information herein are subject to change without notice.

#### SPI MODE FAULT RACE CONDITION

Clearing the SPE bit to disable the SPI can cause an error when transmitting in slave mode. In this situation, a race condition occurs, allowing an invalid mode fault to occur.

Mode faults occur on the SPI when the slave select  $(\overline{SS})$  pin is toggled during a transmission. Mode faults also occur if  $\overline{SS}$  is selected and then unselected before SPSCK returns to its idle level after the shift of the eighth data bit when CPHA = 0 while in slave mode.

When the SPI is disabled, the special port function associated with  $\overline{SS}$  is also disabled and returns to a logic 1. In slave mode,  $\overline{SS}$  must remain a logic 0 during a transmission. Thus, disabling the SPI causes the  $\overline{SS}$  signal to go high internally, which sets up a race for the port logic to send in a logic 1 and the SPI to shut down mode fault detection internally.

This condition can be avoided easily in software if mode faults are disabled by clearing the MODFEN bit of the SPSCR register before disabling the SPI in slave mode.
