description

The TLV5616 is a 12-bit voltage output digital-to-analog converter (DAC) with a flexible 4-wire serial interface. The 4-wire serial interface allows glueless interface to TMS320, SPI, QSPI, and Microwire serial ports. The TLV5616 is programmed with a 16-bit serial string containing 4 control and 12 data bits. Developed for a wide range of supply voltages, the TLV5616 can operate from 2.7 V to 5.5 V.

The resistor string output voltage is buffered by a x2 gain rail-to-rail output buffer. The buffer features a Class AB output stage to improve stability and reduce settling time. The settling time of the DAC is programmable to allow the designer to optimize speed versus power dissipation. The settling time is chosen by the control bits within the 16-bit serial input string. A high-impedance buffer is integrated on the REFIN terminal to reduce the need for a low source impedance drive to the terminal.

Implemented with a CMOS process, the TLV5616 is designed for single supply operation from 2.7 V to 5.5 V. The device is available in an 8-terminal SOIC package. The TLV5616C is characterized for operation from 0°C to 70°C. The TLV5616I is characterized for operation from -40°C to 85°C.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)†

| | |
|--|-----------------------------|
| Supply voltage (V_{DD} to AGND) | 7 V |
| Reference input voltage range | - 0.3 V to $V_{DD} + 0.3$ V |
| Digital input voltage range | - 0.3 V to $V_{DD} + 0.3$ V |
| Operating free-air temperature range, T_A : TLV5616C | 0°C to 70°C |
| TLV5616I | -40°C to 85°C |
| Storage temperature range, T_{stg} | -65°C to 150°C |
| Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds | 260°C |

† Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

recommended operating conditions

| | | MIN | NOM | MAX | UNIT |
|--|-----------------------------|------|-------|----------------|------------|
| Supply voltage, V_{DD} | $V_{DD} = 5$ V | 4.5 | 5 | 5.5 | V |
| | $V_{DD} = 3$ V | 2.7 | 3 | 3.3 | V |
| High-level digital input voltage, V_{IH} | $V_{DD} = 2.7$ V to 5.5 V | 2 | | | V |
| Low-level digital input voltage, V_{IL} | $V_{DD} = 2.7$ V to 5.5 V | | | 0.8 | V |
| Reference voltage, V_{ref} to REFIN terminal | $V_{DD} = 5$ V (see Note 1) | AGND | 2.048 | $V_{DD} - 1.5$ | V |
| Reference voltage, V_{ref} to REFIN terminal | $V_{DD} = 3$ V (see Note 1) | AGND | 1.024 | $V_{DD} - 1.5$ | V |
| Load resistance, R_L | | 2 | 10 | | k Ω |
| Load capacitance, C_L | | | | 100 | pF |
| Clock frequency, f_{CLK} | | | | 20 | MHz |
| Operating free-air temperature, T_A | TLV5616C | 0 | | 70 | °C |
| | TLV5616I | -40 | | 85 | °C |

NOTE 1: Due to the x2 output buffer, a reference input voltage $\geq V_{DD}/2$ causes clipping of the transfer function.

electrical characteristics over recommended operating free-air temperature range (unless otherwise noted)

power supply

| PARAMETER | | TEST CONDITIONS | | MIN | TYP | MAX | UNIT |
|---|------------------------------|--|------------|-----|-----|------|------|
| I_{DD} | Power supply current | $V_{DD} = 5$ V, $V_{REF} = 2.048$ V, No load, All inputs = AGND or V_{DD} , DAC latch = 0x800 | Fast | | 0.9 | 1.35 | mA |
| | | | Slow | | 0.4 | 0.6 | mA |
| | | $V_{DD} = 3$ V, $V_{REF} = 1.024$ V No load, All inputs = AGND or V_{DD} , DAC latch = 0x800 | Fast | | 0.7 | 1.1 | mA |
| | | | Slow | | 0.3 | 0.45 | mA |
| Power down supply current (see Figure 12) | | | | | 10 | | nA |

electrical characteristics over recommended operating free-air temperature range (unless otherwise noted) (continued)

static DAC specifications $R_L = 10\text{ k}\Omega$, $C_L = 100\text{ pF}$

| PARAMETER | | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|--|---|-----------------|-----|-----------|-----------|-----------------|
| Resolution | | | | 12 | 12 | bits |
| INL | Integral nonlinearity | See Note 4 | | ± 1.9 | ± 4 | LSB |
| DNL | Differential nonlinearity | See Note 5 | | ± 0.5 | ± 1 | LSB |
| E _{ZS} | Zero-scale error (offset error at zero scale) | See Note 6 | | | ± 10 | mV |
| Zero-scale-error temperature coefficient | | See Note 7 | | 10 | | ppm/°C |
| E _G | Gain error | See Note 8 | | | ± 0.6 | % of FS voltage |
| Gain-error temperature coefficient | | See Note 9 | | 10 | | ppm/°C |

- NOTES: 4. The relative accuracy or integral nonlinearity (INL) sometimes referred to as linearity error, is the maximum deviation of the output from the line between zero and full scale excluding the effects of zero code and full-scale errors.
5. The differential nonlinearity (DNL) sometimes referred to as differential error, is the difference between the measured and ideal 1 LSB amplitude change of any two adjacent codes. Monotonic means the output voltage changes in the same direction (or remains constant) as a change in the digital input code.
6. Zero-scale error is the deviation from zero voltage output when the digital input code is zero.
7. Zero-scale-error temperature coefficient is given by: $E_{ZS\ TC} = [E_{ZS}(T_{max}) - E_{ZS}(T_{min})]/V_{ref} \times 10^6/(T_{max} - T_{min})$.
8. Gain error is the deviation from the ideal output ($2V_{ref} - 1\text{ LSB}$) with an output load of $10\text{ k}\Omega$ excluding the effects of the zero-error.
9. Gain temperature coefficient is given by: $E_{G\ TC} = [E_G(T_{max}) - E_G(T_{min})]/V_{ref} \times 10^6/(T_{max} - T_{min})$.

| S/N | Signal to noise | | | | 74 | | dB |
| S/(N+D) | Signal to noise + distortion | f _s = 400 KSPS f _{out} = 1.1 kHz, R _L = 10 kΩ, C _L = 100 pF, | | | 66 | | dB |
| THD | Total harmonic distortion | BW = 20 kHz | | | -68 | | dB |
| Spurious free dynamic range | | | | | 70 | | dB |

- NOTES: 11. Settling time is the time for the output signal to remain within ±0.5 LSB of the final measured value for a digital input code change of 0x080 to 0x3FF or 0x3FF to 0x080. Not tested, ensured by design.
 12. Settling time is the time for the output signal to remain within ± 0.5 LSB of the final measured value for a digital input code change of one count. Code change from 0x1FF to 0x200. Not tested, ensured by design.
 13. Slew rate determines the time it takes for a change of the DAC output from 10% to 90% full-scale voltage.

digital input timing requirements

| | | MIN | NOM | MAX | UNIT |
|--------------------------|--|-----|-----|-----|------|
| t _{su} (CS-FS) | Setup time, $\overline{\text{CS}}$ low before FS↓ | 10 | | | ns |
| t _{su} (FS-CK) | Setup time, FS low before first negative SCLK edge | 8 | | | ns |
| t _{su} (C16-FS) | Setup time, sixteenth negative edge after FS low on which bit D0 is sampled before rising edge of FS | 10 | | | ns |
| t _{su} (C16-CS) | Setup time, sixteenth positive SCLK edge (first positive after D0 is sampled) before $\overline{\text{CS}}$ rising edge. If FS is used instead of the sixteenth positive edge to update the DAC, then the setup time is between the FS rising edge and CS rising edge. | 10 | | | ns |
| t _{wH} | Pulse duration, SCLK high | 25 | | | ns |
| t _{wL} | Pulse duration, SCLK low | 25 | | | ns |
| t _{su} (D) | Setup time, data ready before SCLK falling edge | 8 | | | ns |
| t _h (D) | Hold time, data held valid after SCLK falling edge | 5 | | | ns |
| t _{wH} (FS) | Pulse duration, FS high | 20 | | | ns |

APPLICATION INFORMATION

general function

The TLV5616 is a 12-bit single supply DAC based on a resistor string architecture. The device consists of a serial interface, speed and power-down control logic, a reference input buffer, a resistor string, and a rail-to-rail output buffer.

The output voltage (full scale determined by external reference) is given by:

$$2 \text{ REF} \frac{\text{CODE}}{0x1000} \text{ [V]}$$

Where REF is the reference voltage and CODE is the digital input value within the range of 0x000 to 0xFFF. A power-on reset initially resets the internal latches to a defined state (all bits zero).

serial interface

Explanation of data transfer: First, the device has to be enabled with $\overline{\text{CS}}$ set to low. Then, a falling edge of FS starts shifting the data bit-per-bit (starting with the MSB) to the internal register on the falling edges of SCLK. After 16 bits have been transferred or FS rises, the content of the shift register is moved to the DAC latch which updates the voltage output to the new level.

The serial interface of the TLV5616 can be used in two basic modes:

- Four wire (with chip select)
- Three wire (without chip select)

Using chip select (four wire mode), it is possible to have more than one device connected to the serial port of the data source (DSP or microcontroller). The interface is compatible with the TMS320 family. Figure 15 shows an example with two TLV5616s connected directly to a TMS320 DSP.

CONVERTERS WITH POWER DOWN

SLAS152A – DECEMBER 1997 – REVISED SEPTEMBER 1998

APPLICATION INFORMATION

serial interface (continued)

If there is no need to have more than one device on the serial bus, then \overline{CS} can be tied low. Figure 16 shows an example of how to connect the TLV5616 to a TMS320, SPI, or Microwire port using only three pins.

Figure 16. Three-Wire Interface

Notes on SPI and Microwire: Before the controller starts the data transfer, the software has to generate a falling edge on the I/O pin connected to FS. If the word width is 8 bits (SPI and Microwire), two write operations must be performed to program the TLV5616. After the write operation(s), the DAC output is updated automatically on the sixteenth positive clock edge.

serial clock frequency and update rate

The maximum serial clock frequency is given by:

$$f_{SCLKmax} = \frac{1}{t_{wH(min)} + t_{wL(min)}} = 20 \text{ MHz}$$

The maximum update rate is:

$$f_{UPDATEmax} = \frac{1}{16 (t_{wH(min)} + t_{wL(min)})} = 1.25 \text{ MHz}$$

The maximum update rate is a theoretical value for the serial interface, since the settling time of the TLV5616 has to be considered also.

data format

The 16-bit data word for the TLV5616 consists of two parts:

- Control bits (D15 . . . D12)
- New DAC value (D11 . . . D0)

| | | | | | | | | | | | | | | | |
|-----|-----|-----|-----|-------------------------|-----|----|----|----|----|----|----|----|----|----|----|
| D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| X | SPD | PWR | X | New DAC value (12 bits) | | | | | | | | | | | |

X: don't care

SPD: Speed control bit. 1 → fast mode 0 → slow mode

PWR: Power control bit. 1 → power down 0 → normal operation

In power down mode, all amplifiers within the TLV5616 are disabled.

APPLICATION INFORMATION

TLV5616 interfaced to TMS320C203 DSP

hardware interfacing

Figure 17 shows an example how to connect the TLV5616 to a TMS320C203 DSP. The serial interface of the TLV5616 is ideally suited to this configuration, using a maximum of four wires to make the necessary connections. In applications where only one synchronous serial peripheral is used, the interface can be simplified even further by pulling \overline{CS} low all the time as shown in the figure.

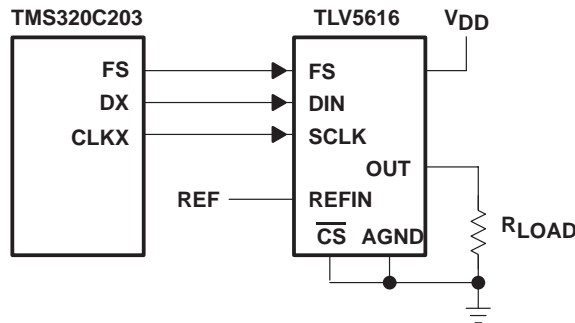

Figure 17. TLV5616 to DSP Interface

software

No setup procedure is needed to access the TLV5616. The output voltage can be set using just a single command.

```
out    data_addr, SDTR
```

Where data_addr points to an address location holding the control bits and the 12 data bits providing the output voltage data. SDTR is the address of the transmit FIFO of the synchronous serial port.

The following code shows how to use the timer of the TMS320C203 as a time base to generate a voltage ramp with the TLV5616.

A timer interrupt is generated every 205 μ s. The corresponding interrupt service routine increments the output code (stored at 0x0064) for the DAC, adds the DAC control bits to the four most significant bits, and writes the new code to the TLV5616. The resulting period of the saw waveform is:

$$\pi = 4096 \times 205 \text{ E-6 s} = 0.84 \text{ s}$$

```

APPLICATION INFORMATION

TLV5616 interfaced to MCS51[®] microcontroller

hardware interfacing

Figure 18 shows an example of how to connect the TLV5616 to an MCS51[®] compatible microcontroller. The serial DAC input data and external control signals are sent via I/O port 3 of the controller. The serial data is sent on the RxD line, with the serial clock output on the TxD line. P3.4 and P3.5 are configured as outputs to provide the chip select and frame sync signals for the TLV5616.

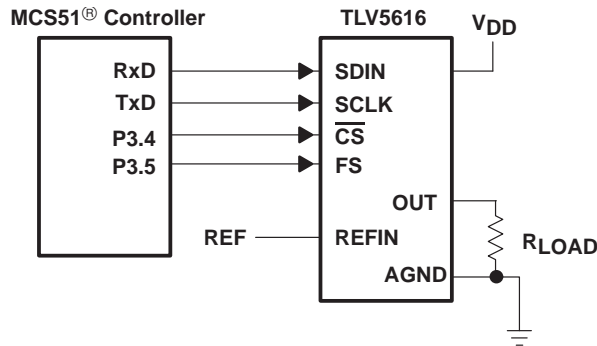

Figure 18. TLV5616 to MCS51[®] Controller Interface

software

The example program puts out a sine wave on the OUT pin.

The on-chip timer is used to generate interrupts at a fixed frequency. The related interrupt service routine fetches and writes the next sample to the DAC. The samples are stored in a lookup table, which describes one full period of a sine wave.

The serial port of the controller is used in mode 0, which transmits 8 bits of data on RxD, accompanied by a synchronous clock on TxD. Two writes concatenated together are required to write a complete word to the TLV5616. The CS and FS signals are provided in the required fashion through control of I/O port 3, which has bit addressable outputs.

```

2.7 V TO 5.5 V LOW POWER 12-BIT DIGITAL-TO-ANALOG CONVERTERS WITH POWER DOWN

SLAS152A – DECEMBER 1997 – REVISED SEPTEMBER 1998

APPLICATION INFORMATION

linearity, offset, and gain error using single ended supplies

When an amplifier is operated from a single supply, the voltage offset can still be either positive or negative. With a positive offset, the output voltage changes on the first code change. With a negative offset, the output voltage may not change with the first code, depending on the magnitude of the offset voltage.

The output amplifier attempts to drive the output to a negative voltage. However, because the most negative supply rail is ground, the output cannot drive below ground and clamps the output at 0 V.

The output voltage then remains at zero until the input code value produces a sufficient positive output voltage to overcome the negative offset voltage, resulting in the transfer function shown in Figure 19.

Figure 19. Effect of Negative Offset (Single Supply)

This offset error, not the linearity error, produces this breakpoint. The transfer function would have followed the dotted line if the output buffer could drive below the ground rail.

For a DAC, linearity is measured between zero-input code (all inputs 0) and full-scale code (all inputs 1) after offset and full scale are adjusted out or accounted for in some way. However, single supply operation does not allow for adjustment when the offset is negative due to the breakpoint in the transfer function. So the linearity is measured between full-scale code and the lowest code that produces a positive output voltage.

power-supply bypassing and ground management

Printed circuit boards that use separate analog and digital ground planes offer the best system performance. Wire-wrap boards do not perform well and should not be used. The two ground planes should be connected together at the low-impedance power-supply source. The best ground connection may be achieved by connecting the DAC AGND terminal to the system analog ground plane making sure that analog ground currents are well managed and there are negligible voltage drops across the ground plane.

A 0.1- μ F ceramic-capacitor bypass should be connected between V_{DD} and AGND and mounted with short leads as close as possible to the device. Use of ferrite beads may further isolate the system analog supply from the digital power supply.

Figure 20 shows the ground plane layout and bypassing technique.

Figure 20. Power-Supply Bypassing

APPLICATION INFORMATION

definitions of specifications and terminology

integral nonlinearity (INL)

The relative accuracy or integral nonlinearity (INL), sometimes referred to as linearity error, is the maximum deviation of the output from the line between zero and full scale excluding the effects of zero code and full-scale errors.

differential nonlinearity (DNL)

The differential nonlinearity (DNL), sometimes referred to as differential error, is the difference between the measured and ideal 1 LSB amplitude change of any two adjacent codes. Monotonic means the output voltage changes in the same direction (or remains constant) as a change in the digital input code.

zero-scale error (E_{ZS})

Zero-scale error is defined as the deviation of the output from 0 V at a digital input value of 0.

gain error (E_G)

Gain error is the error in slope of the DAC transfer function.

signal-to-noise ratio + distortion (S/N+D)

S/N+D is the ratio of the rms value of the output signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

spurious free dynamic range (SFDR)

SFDR is the difference between the rms value of the output signal and the rms value of the largest spurious signal within a specified bandwidth. The value for SFDR is expressed in decibels.

total harmonic distortion (THD)

THD is the ratio of the rms sum of the first six harmonic components to the rms value of the fundamental signal and is expressed in decibels.

IMPORTANT NOTICE

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgement, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

CERTAIN APPLICATIONS USING SEMICONDUCTOR PRODUCTS MAY INVOLVE POTENTIAL RISKS OF DEATH, PERSONAL INJURY, OR SEVERE PROPERTY OR ENVIRONMENTAL DAMAGE ("CRITICAL APPLICATIONS"). TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS. INCLUSION OF TI PRODUCTS IN SUCH APPLICATIONS IS UNDERSTOOD TO BE FULLY AT THE CUSTOMER'S RISK.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards must be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance or customer product design. TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used. TI's publication of information regarding any third party's products or services does not constitute TI's approval, warranty or endorsement thereof.
