SLFS047B – FEBRUARY 1984 – REVISED SEPTEMBER 1997

- Very Low Power Consumption . . . 2 mW Typ at V_{DD} = 5 V
- Capable of Operation in Astable Mode
- CMOS Output Capable of Swinging Rail to Rail
- High Output-Current Capability Sink 100 mA Typ Source 10 mA Typ
- Output Fully Compatible With CMOS, TTL, and MOS
- Low Supply Current Reduces Spikes During Output Transitions
- Single-Supply Operation From 2 V to 15 V
- Functionally interchangeable With the NE556; Has Same Pinout

description

The TLC556 series are monolithic timing circuits fabricated using the TI LinCMOS[™] process, which provides full compatibility with CMOS, TTL, and MOS logic and operates at frequencies up to 2 MHz. Accurate time delays and oscillations are possible with smaller, less-expensive timing capacitors than the NE556 because of the high input impedance. Power consumption is low across the full range of power supply voltages.

Like the NE556, the TLC556 has a trigger level approximately one-third of the supply voltage and

a threshold level approximately two-thirds of the supply voltage. These levels can be altered by use of the control voltage terminal. When the trigger input falls below the trigger level, the flip-flop is set and the output goes high. If the trigger input is above the trigger level and the threshold input is above the threshold level, the flip-flop is reset and the output is low. The reset input can override all other inputs and can be used to initiate a new timing cycle. If the reset input is low, the flip-flop is reset and the output is low. Whenever the output is low, a low-impedance path is provided between the discharge terminal and ground.

While the CMOS output is capable of sinking over 100 mA and sourcing over 10 mA, the TLC556 exhibits greatly reduced supply-current spikes during output transitions. This minimizes the need for the large decoupling capacitors required by the NE556.

These devices have internal electrostatic-discharge (ESD) protection circuits that prevent catastrophic failures at voltages up to 2000 V as tested under MIL-STD-883C, Method 3015. However, care should be exercised in handling these devices, as exposure to ESD may result in degradation of the device parametric performance.

All unused inputs should be tied to an appropriate logic level to prevent false triggering.

The TLC556C is characterized for operation from 0°C to 70°C. The TLC556I is characterized for operation from -40°C to 85°C. The TLC556M is characterized for operation over the full military temperature range of -55°C to 125°C.

LinCMOS is a trademark of Texas Instruments Incorporated.

functional block diagram (each timer)

RESET can override TRIG and THRES. TRIG can override THRES.

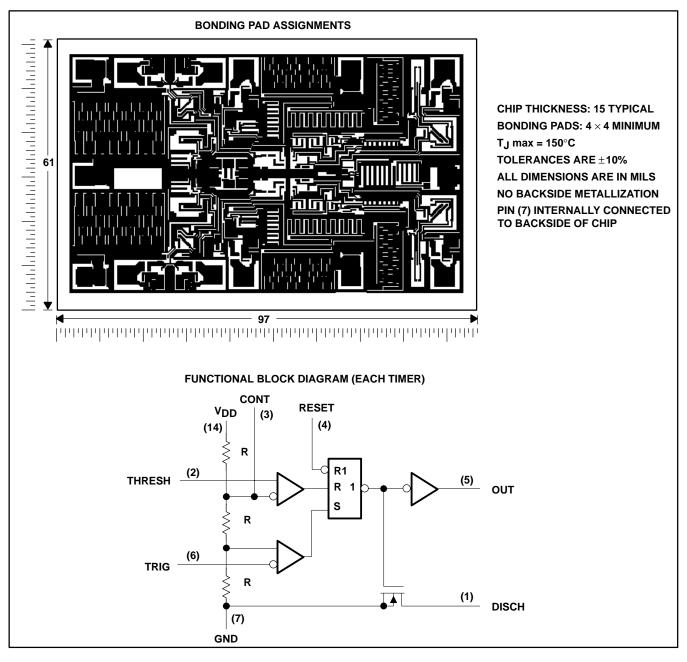

Pin numbers shown are for the D, J, or N packages.

SLFS047B - FEBRUARY 1984 - REVISED SEPTEMBER 1997

TLC556Y chip information

These chips, properly assembled, display characteristics similar to the TLC556 (see electrical table). Thermal compression or ultrasonic bonding may be used on the doped aluminum bonding pads. Chips may be mounted with conductive epoxy or a gold-silicon preform.

[‡]The effects of the load resistance on these values must be taken into account separately.

Figure 2

SLFS047B – FEBRUARY 1984 – REVISED SEPTEMBER 1997

APPLICATION INFORMATION

Figure 3. Astable Operation

Connecting the trigger input to the threshold input, as shown in Figure 3, causes the timer to run as a multivibrator. The capacitor C_T charges through R_A and R_B to the threshold voltage level (approximately 0.67 V_{DD}) and then discharges through R_B only to the value of the trigger voltage level (approximately 0.33 V_{DD}). The output is high during the charging cycle (t_H) and low during the discharge cycle (t_L). The duty cycle is controlled by the values of R_A , and R_B , and C_T , as shown in the equations below.

$$t_{H} \approx C_{T} (R_{A} + R_{B}) \text{ In } 2 \quad (\text{In } 2 = 0.693)$$

$$t_{L} \approx C_{T} R_{B} \text{ In } 2$$
Period = $t_{H} + t_{L} \approx C_{T} (R_{A} + 2R_{B}) \text{ In } 2$
Output driver duty cycle = $\frac{t_{L}}{t_{H} + t_{L}} \approx 1 - \frac{R_{B}}{R_{A} + 2R_{B}}$
Output waveform duty cycle = $\frac{t_{H}}{t_{H} + t_{L}} \approx \frac{R_{B}}{R_{A} + 2R_{B}}$

The 0.1-µF capacitor at CONT in Figure 3 decreases the period by about 10%.

The formulas shown above do not allow for any propagation delay from the trigger and threshold inputs to the discharge output. These delay times add directly to the period and create differences between calculated and actual values that increase with frequency. In addition, the discharge output resistance r_{on} adds to R_B to provide another source of error in the calculation when R_B is very low or r_{on} is very high.

The equations below provide better agreement with measured values.

$$t_{\rm H} = C_{\rm T} (R_{\rm A} + R_{\rm B}) \ln \left[3 - \exp\left(\frac{-t_{\rm PLH}}{C_{\rm T} (R_{\rm B} + r_{\rm on})}\right) \right] + t_{\rm PHL}$$
$$t_{\rm L} = C_{\rm T} (R_{\rm B} + r_{\rm on}) \ln \left[3 - \exp\left(\frac{-t_{\rm PHL}}{C_{\rm T} (R_{\rm A} + R_{\rm B})}\right) \right] + t_{\rm PLH}$$

SLFS047B - FEBRUARY 1984 - REVISED SEPTEMBER 1997

APPLICATION INFORMATION

The preceding equations and those given earlier are similar in that a time constant is multiplied by the logarithm of a number or function. The limit values of the logarithmic terms must be between In 2 at low frequencies and In 3 at extremely high frequencies. For a duty cycle close to 50%, an appropriate constant for the logarithmic

terms can be substituted with good results. Duty cycles less than 50% $\frac{t_{H}}{t_{H} + t_{L}}$ will require that $\frac{t_{H}}{t_{L}}$ <1 and

possibly $R_A \le r_{on}$. These conditions can be difficult to obtain.

In monostable applications, the trip point of the trigger input can be set by a voltage applied to CONT. An input voltage between 10% and 80% of the supply voltage from a resistor divider with at least 500- μ A bias provides good results.
