

# TPA301 350-mW LOW-VOLTAGE AUDIO POWER AMPLIFIER

SLOS208B – JANUARY 1998 – REVISED OCTOBER 1998

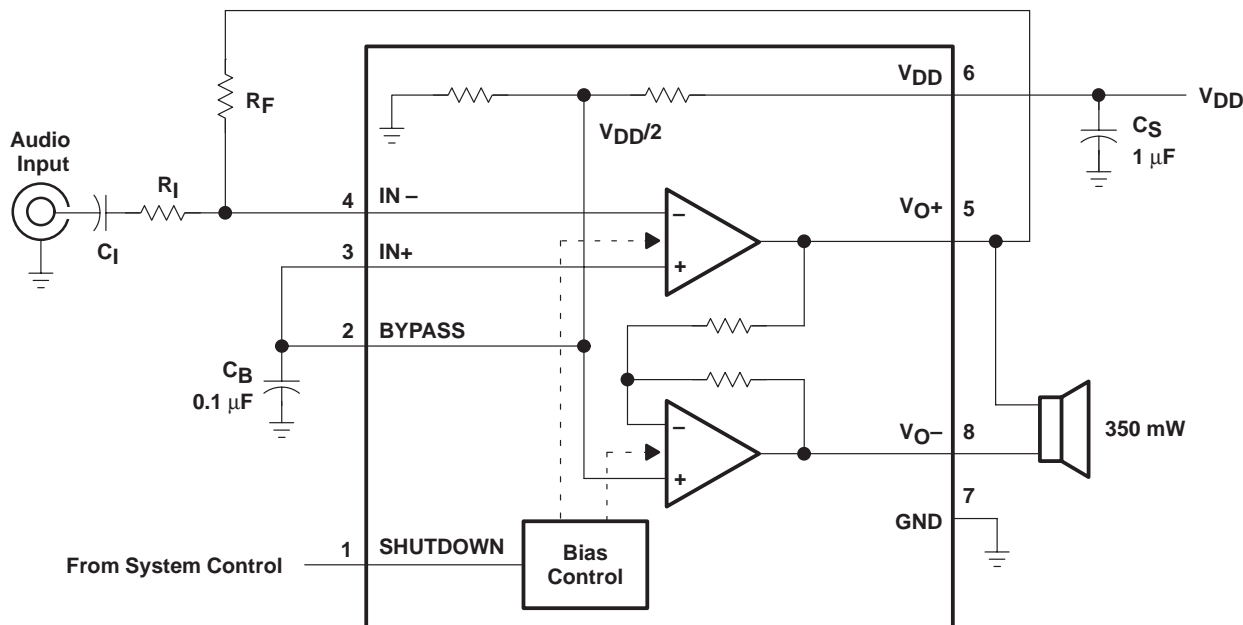

- Fully Specified for 3.3-V and 5-V Operation
- Wide Power Supply Compatibility  
2 V – 5.5 V
- Output Power for  $R_L = 8 \Omega$ 
  - 350 mW at  $V_{DD} = 5 \text{ V}$ , BTL
  - 250 mW at  $V_{DD} = 3.3 \text{ V}$ , BTL
- Ultra-Low Quiescent Current in Shutdown Mode . . . 0.15  $\mu\text{A}$
- Thermal and Short-Circuit Protection
- Surface Mount Packaging
  - SOIC
  - PowerPAD™ MSOP

D AND DGN PACKAGE  
(TOP VIEW)

## description

The TPA301 is a bridge-tied load (BTL) audio power amplifier developed especially for low-voltage applications where internal speakers are required. Operating with a 3.3-V supply, the TPA301 can deliver 250-mW of continuous power into a BTL 8- $\Omega$  load at less than 1% THD+N throughout voice band frequencies. Although this device is characterized out to 20 kHz, its operation was optimized for narrower band applications such as cellular communications. The BTL configuration eliminates the need for external coupling capacitors on the output in most applications, which is particularly important for small battery-powered equipment. This device features a shutdown mode for power-sensitive applications with a quiescent current of 0.15  $\mu\text{A}$  during shutdown. The TPA301 is available in an 8-pin SOIC surface-mount package and the surface-mount PowerPAD MSOP, which reduces board space by 50% and height by 40%.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PowerPAD is a trademark of Texas Instruments Incorporated.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

## 350-mW LOW-VOLTAGE AUDIO POWER AMPLIFIER

SLOS208B – JANUARY 1998 – REVISED OCTOBER 1998

### AVAILABLE OPTIONS

T <sub>A</sub>	PACKAGED DEVICES		MSOP Symbolization
	SMALL OUTLINE† (D)	MSOP† (DGN)	
–40°C to 85°C	TPA301D	TPA301DGN	AAA

† The D and DGN packages are available taped and reeled. To order a taped and reeled part, add the suffix R to the part number (e.g., TPA301DR).

### Terminal Functions

TERMINAL NAME	NO.	I/O	DESCRIPTION
BYPASS	2	I	BYPASS is the tap to the voltage divider for internal mid-supply bias. This terminal should be connected to a 0.1-μF to 1-μF capacitor when used as an audio amplifier.
GND	7		GND is the ground connection.
IN–	4	I	IN– is the inverting input. IN– is typically used as the audio input terminal.
IN+	3	I	IN+ is the noninverting input. IN+ is typically tied to the BYPASS terminal.
SHUTDOWN	1	I	SHUTDOWN places the entire device in shutdown mode when held high (I <sub>DD</sub> < 1 μA).
V <sub>DD</sub>	6		V <sub>DD</sub> is the supply voltage terminal.
V <sub>O+</sub>	5	O	V <sub>O+</sub> is the positive BTL output.
V <sub>O–</sub>	8	O	V <sub>O–</sub> is the negative BTL output.

### absolute maximum ratings over operating free-air temperature range (unless otherwise noted)‡

Supply voltage, V <sub>DD</sub>	6 V
Input voltage, V <sub>I</sub>	–0.3 V to V <sub>DD</sub> + 0.3 V
Continuous total power dissipation	internally limited (see Dissipation Rating Table)
Operating free-air temperature range, T <sub>A</sub>	–40°C to 85°C
Operating junction temperature range, T <sub>J</sub>	–40°C to 150°C
Storage temperature range, T <sub>stg</sub>	–65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

‡ Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

### DISSIPATION RATING TABLE

PACKAGE	T <sub>A</sub> ≤ 25°C	DERATING FACTOR	T <sub>A</sub> = 70°C	T <sub>A</sub> = 85°C

## APPLICATION INFORMATION

### bridge-tied load

Figure 23 shows a linear audio power amplifier (APA) in a BTL configuration. The TPA301 BTL amplifier consists of two linear amplifiers driving both ends of the load. There are several potential benefits to this differential drive configuration but power to the load should be initially considered. The differential drive to the speaker means that as one side is slewing up, the other side is slewing down, and vice versa. This in effect doubles the voltage swing on the load as compared to a ground referenced load. Plugging  $2 \times V_{O(PP)}$  into the power equation, where voltage is squared, yields  $4 \times$  the output power from the same supply rail and load impedance (see equation 1).

$$V_{(rms)} = \frac{V_{O(PP)}}{2\sqrt{2}}$$

$$\text{Power} = \frac{V_{(rms)}^2}{R_L} \tag{1}$$

**Figure 23. Bridge-Tied Load Configuration**

In a typical portable handheld equipment sound channel operating at 3.3 V, bridging raises the power into an 8-Ω speaker from a single-ended (SE, ground reference) limit of 62.5 mW to 250 mW. In sound power that is a 6-dB improvement — which is loudness that can be heard. In addition to increased power, there are frequency response concerns. Consider the single-supply SE configuration shown in Figure 24. A coupling capacitor is required to block the dc offset voltage from reaching the load. These capacitors can be quite large (approximately 33 μF to 1000 μF) so they tend to be expensive, heavy, occupy valuable PCB area, and have the additional drawback of limiting low-frequency performance of the system. This frequency limiting effect is due to the high pass filter network created with the speaker impedance and the coupling capacitance and is calculated with equation 2.

APPLICATION INFORMATION

bridge-tied load versus single-ended mode (continued)

$$f_{(\text{corner})} = \frac{1}{2\pi R_L C_C} \tag{2}$$

For example, a 68-μF capacitor with an 8-Ω speaker would attenuate low frequencies below 293 Hz. The BTL configuration cancels the dc offsets, eliminating the need for the blocking capacitors. Low-frequency performance is then limited only by the input network and speaker response. Cost and PCB space are also minimized by eliminating the bulky coupling capacitor.

Figure 24. Single-Ended Configuration and Frequency Response

Increasing power to the load does carry a penalty of increased internal power dissipation. The increased dissipation is understandable considering that the BTL configuration produces 4× the output power of a SE configuration. Internal dissipation versus output power is discussed further in the *thermal considerations* section.

BTL amplifier efficiency

Linear amplifiers are notoriously inefficient. The primary cause of these inefficiencies is voltage drop across the output stage transistors. There are two components of the internal voltage drop. One is the headroom or dc voltage drop that varies inversely to output power. The second component is due to the sinewave nature of the output. The total voltage drop can be calculated by subtracting the RMS value of the output voltage from VDD. The internal voltage drop multiplied by the RMS value of the supply current, IDDrms, determines the internal power dissipation of the amplifier.

An easy-to-use equation to calculate efficiency starts out as being equal to the ratio of power from the power supply to the power delivered to the load. To accurately calculate the RMS values of power in the load and in the amplifier, the current and voltage waveform shapes must first be understood (see Figure 25).

Figure 25. Voltage and Current Waveforms for BTL Amplifiers

## APPLICATION INFORMATION

### BTL amplifier efficiency (continued)

Although the voltages and currents for SE and BTL are sinusoidal in the load, currents from the supply are very different between SE and BTL configurations. In an SE application the current waveform is a half-wave rectified shape whereas in BTL it is a full-wave rectified waveform. This means RMS conversion factors are different. Keep in mind that for most of the waveform both the push and pull transistors are not on at the same time, which supports the fact that each amplifier in the BTL device only draws current from the supply for half the waveform. The following equations are the basis for calculating amplifier efficiency.

$$\text{Efficiency} = \frac{P_L}{P_{\text{SUP}}} \quad (3)$$

where:

$$P_L = \frac{V_{L\text{rms}}^2}{R_L} = \frac{V_p^2}{2R_L}$$

$$V_{L\text{rms}} = \frac{V_P}{\sqrt{2}}$$

$$P_{\text{SUP}} = V_{\text{DD}} I_{\text{DDrms}} = \frac{V_{\text{DD}} 2V_P}{\pi R_L}$$

$$I_{\text{DDrms}} = \frac{2V_P}{\pi R_L}$$

$$\text{Efficiency of a BTL Configuration} = \frac{\pi V_P}{2V_{\text{DD}}} = \frac{\pi \left( \frac{P_L R_L}{2} \right)^{1/2}}{2V_{\text{DD}}} \quad (4)$$

Table 1 employs equation 4 to calculate efficiencies for three different output power levels. The efficiency of the amplifier is quite low for lower power levels and rises sharply as power to the load is increased resulting in a nearly flat internal power dissipation over the normal operating range. The internal dissipation at full output power is less than in the half power range. Calculating the efficiency for a specific system is the key to proper power supply design.

**Table 1. Efficiency Vs Output Power in 3.3-V 8-Ω BTL Systems**

Output Power (W)	Efficiency (%)	Peak-to-Peak Voltage (V)	Internal Dissipation (W)
0.125	33.6	1.41	0.26
0.25	47.6	2.00	0.29
0.375	58.3	2.45†	0.28

† High-peak voltage values cause the THD to increase.

A final point to remember about linear amplifiers (either SE or BTL) is how to manipulate the terms in the efficiency equation to utmost advantage when possible. Note that in equation 4,  $V_{\text{DD}}$  is in the denominator. This indicates that as  $V_{\text{DD}}$  goes down, efficiency goes up.

# TPA301

## 350-mW LOW-VOLTAGE AUDIO POWER AMPLIFIER

SLOS208B – JANUARY 1998 – REVISED OCTOBER 1998

### APPLICATION INFORMATION

#### application schematic

Figure 26 is a schematic diagram of a typical handheld audio application circuit, configured for a gain of  $-10$  V/V.

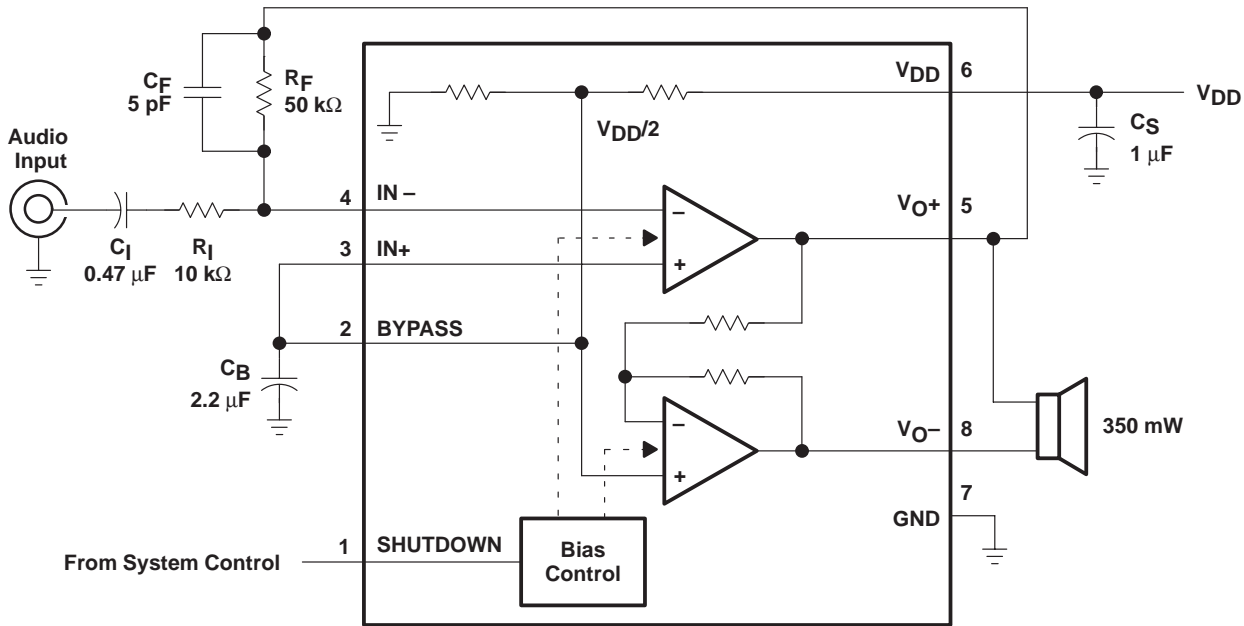

Figure 26. TPA301 Application Circuit

The following sections discuss the selection of the components used in Figure 26.

#### component selection

##### gain setting resistors, $R_F$ and $R_I$

The gain for each audio input of the TPA301 is set by resistors  $R_F$  and  $R_I$  according to equation 5 for BTL mode.

$$\text{BTL Gain} = A_V = -2 \left( \frac{R_F}{R_I} \right) \quad (5)$$

BTL mode operation brings about the factor 2 in the gain equation due to the inverting amplifier mirroring the voltage swing across the load. Given that the TPA301 is a MOS amplifier, the input impedance is very high, consequently input leakage currents are not generally a concern although noise in the circuit increases as the value of  $R_F$  increases. In addition, a certain range of  $R_F$  values are required for proper start-up operation of the amplifier. Taken together it is recommended that the effective impedance seen by the inverting node of the amplifier be set between  $5 \text{ k}\Omega$  and  $20 \text{ k}\Omega$ . The effective impedance is calculated in equation 6.

$$\text{Effective Impedance} = \frac{R_F R_I}{R_F + R_I} \quad (6)$$

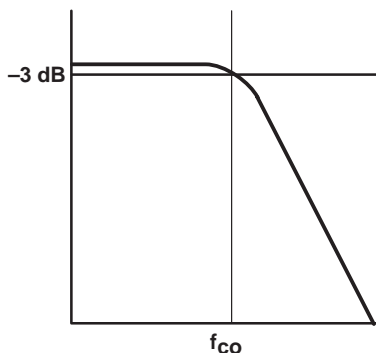

## APPLICATION INFORMATION

### component selection (continued)

As an example, consider an input resistance of 10 kΩ and a feedback resistor of 50 kΩ. The BTL gain of the amplifier would be –10 V/V, and the effective impedance at the inverting terminal would be 8.3 kΩ, which is well within the recommended range.

For high performance applications metal film resistors are recommended because they tend to have lower noise levels than carbon resistors. For values of  $R_F$  above 50 kΩ the amplifier tends to become unstable due to a pole formed from  $R_F$  and the inherent input capacitance of the MOS input structure. For this reason, a small compensation capacitor,  $C_F$ , of approximately 5 pF should be placed in parallel with  $R_F$  when  $R_F$  is greater than 50 kΩ. This, in effect, creates a low pass filter network with the cutoff frequency defined in equation 7.

$$f_{co(\text{lowpass})} = \frac{1}{2\pi R_F C_F} \quad (7)$$

For example, if  $R_F$  is 100 kΩ and  $C_F$  is 5 pF then  $f_{co}$  is 318 kHz, which is well outside of the audio range.

### input capacitor, $C_I$

In the typical application an input capacitor,  $C_I$ , is required to allow the amplifier to bias the input signal to the proper dc level for optimum operation. In this case,  $C_I$  and  $R_I$  form a high-pass filter with the corner frequency determined in equation 8.

$$f_{co(\text{highpass})} = \frac{1}{2\pi R_I C_I} \quad (8)$$

The value of  $C_I$  is important to consider as it directly affects the bass (low frequency) performance of the circuit. Consider the example where  $R_I$  is 10 kΩ and the specification calls for a flat bass response down to 40 Hz. Equation 8 is reconfigured as equation 9.

$$C_I = \frac{1}{2\pi R_I f_{co}} \quad (9)$$

# TPA301

## 350-mW LOW-VOLTAGE AUDIO POWER AMPLIFIER

SLOS208B – JANUARY 1998 – REVISED OCTOBER 1998

### APPLICATION INFORMATION

#### component selection (continued)

In this example,  $C_I$  is  $0.40 \mu\text{F}$  so one would likely choose a value in the range of  $0.47 \mu\text{F}$  to  $1 \mu\text{F}$ . A further consideration for this capacitor is the leakage path from the input source through the input network ( $R_I$ ,  $C_I$ ) and the feedback resistor ( $R_F$ ) to the load. This leakage current creates a dc offset voltage at the input to the amplifier that reduces useful headroom, especially in high gain applications. For this reason a low-leakage tantalum or ceramic capacitor is the best choice. When polarized capacitors are used, the positive side of the capacitor should face the amplifier input in most applications, as the dc level there is held at  $V_{DD}/2$ , which is likely higher than the source dc level. It is important to confirm the capacitor polarity in the application.

#### power supply decoupling, $C_S$

The TPA301 is a high-performance CMOS audio amplifier that requires adequate power supply decoupling to ensure the output total harmonic distortion (THD) is as low as possible. Power supply decoupling also prevents oscillations for long lead lengths between the amplifier and the speaker. The optimum decoupling is achieved by using two capacitors of different types that target different types of noise on the power supply leads. For higher frequency transients, spikes, or digital hash on the line, a good low equivalent-series-resistance (ESR) ceramic capacitor, typically  $0.1 \mu\text{F}$ , placed as close as possible to the device  $V_{DD}$  lead, works best. For filtering lower-frequency noise signals, a larger aluminum electrolytic capacitor of  $10 \mu\text{F}$  or greater placed near the audio power amplifier is recommended.

#### midrail bypass capacitor, $C_B$

The midrail bypass capacitor,  $C_B$ , is the most critical capacitor and serves several important functions. During start-up or recovery from shutdown mode,  $C_B$  determines the rate at which the amplifier starts up. The second function is to reduce noise produced by the power supply caused by coupling into the output drive signal. This noise is from the midrail generation circuit internal to the amplifier, which appears as degraded PSRR and THD + N. The capacitor is fed from a  $250\text{-k}\Omega$  source inside the amplifier. To keep the start-up pop as low as possible, the relationship shown in equation 10 should be maintained, which insures the input capacitor is fully charged before the bypass capacitor is fully charged and the amplifier starts up.

$$\frac{10}{(C_B \times 250 \text{ k}\Omega)} \leq \frac{1}{(R_F + R_I) C_I} \quad (10)$$

As an example, consider a circuit where  $C_B$  is  $2.2 \mu\text{F}$ ,  $C_I$  is  $0.47 \mu\text{F}$ ,  $R_F$  is  $50 \text{ k}\Omega$  and  $R_I$  is  $10 \text{ k}\Omega$ . Inserting these values into the equation 10 we get:

$$18.2 \leq 35.5$$

which satisfies the rule. Bypass capacitor,  $C_B$ , values of  $2.2 \mu\text{F}$  to  $1 \mu\text{F}$  ceramic or tantalum **low-ESR** capacitors are recommended for the best THD and noise performance.

#### using low-ESR capacitors

Low-ESR capacitors are recommended throughout this application. A real (as opposed to ideal) capacitor can be modeled simply as a resistor in series with an ideal capacitor. The voltage drop across this resistor minimizes the beneficial effects of the capacitor in the circuit. The lower the equivalent value of this resistance, the more the real capacitor behaves like an ideal capacitor.

POST OFFICE BOX 655303 • DALLAS, TEXAS 75265

## APPLICATION INFORMATION

### 5-V versus 3.3-V operation

The TPA301 operates over a supply range of 2 V to 5.5 V. This data sheet provides full specifications for 5-V and 3.3-V operation, as these are considered to be the two most common standard voltages. There are no special considerations for 3.3-V versus 5-V operation with respect to supply bypassing, gain setting, or stability. The most important consideration is that of output power. Each amplifier in TPA301 can produce a maximum voltage swing of  $V_{DD} - 1$  V. This means, for 3.3-V operation, clipping starts to occur when  $V_{O(PP)} = 2.3$  V as opposed to  $V_{O(PP)} = 4$  V at 5 V. The reduced voltage swing subsequently reduces maximum output power into an 8- $\Omega$  load before distortion becomes significant.

Operation from 3.3-V supplies, as can be shown from the efficiency formula in equation 4, consumes approximately two-thirds the supply power for a given output-power level than operation from 5-V supplies.

### headroom and thermal considerations

Linear power amplifiers dissipate a significant amount of heat in the package under normal operating conditions. A typical music CD requires 12 dB to 15 dB of dynamic headroom to pass the loudest portions without distortion as compared with the average power output. From the TPA301 data sheet, one can see that when the TPA301 is operating from a 5-V supply into a 8- $\Omega$  speaker 350 mW peaks are available. Converting Watts to dB:

$$\begin{aligned} P_{dB} &= 10\text{Log}P_W \\ &= 10\text{Log}350 \text{ mW} \\ &= -4.6 \text{ dB} \end{aligned}$$

Subtracting the headroom restriction to obtain the average listening level without distortion yields:

$$\begin{aligned} -4.6 \text{ dB} - 15 \text{ dB} &= -19.6 \text{ dB (15 dB headroom)} \\ -4.6 \text{ dB} - 12 \text{ dB} &= -16.6 \text{ dB (12 dB headroom)} \\ -4.6 \text{ dB} - 9 \text{ dB} &= -13.6 \text{ dB (9 dB headroom)} \\ -4.6 \text{ dB} - 6 \text{ dB} &= -10.6 \text{ dB (6 dB headroom)} \\ -4.6 \text{ dB} - 3 \text{ dB} &= -7.6 \text{ dB (3 dB headroom)} \end{aligned}$$

Converting dB back into watts:

$$\begin{aligned} P_W &= 10^{P_{dB}/10} \\ &= 11 \text{ mW (15 dB headroom)} \\ &= 22 \text{ mW (12 dB headroom)} \\ &= 44 \text{ mW (9 dB headroom)} \\ &= 88 \text{ mW (6 dB headroom)} \\ &= 175 \text{ mW (3 dB headroom)} \end{aligned}$$

## 350-mW LOW-VOLTAGE AUDIO POWER AMPLIFIER

SLOS208B – JANUARY1998 – REVISED OCTOBER 1998

---

### APPLICATION INFORMATION

#### headroom and thermal considerations (continued)

This is valuable information to consider when attempting to estimate the heat dissipation requirements for the amplifier system. Comparing the absolute worst case, which is 350 mW of continuous power output with 0 dB of headroom, against 12 dB and 15 dB applications drastically affects maximum ambient temperature ratings for the system. Using the power dissipation curves for a 5-V, 8- $\Omega$  system, the internal dissipation in the TPA301 and maximum ambient temperatures is shown in Table 2.

**Table 2. TPA301 Power Rating, 5-V, 8- $\Omega$ , BTL**

PEAK OUTPUT POWER (mW)	AVERAGE OUTPUT POWER	POWER DISSIPATION (mW)	MAXIMUM AMBIENT TEMPERATURE
			0 CFM
350	350 mW	600	46°C
350	175 mW (3 dB)	500	64°C
350	88 mW (6 dB)	380	85°C
350	44 mW (9 dB)	300	98°C
350	22 mW (12 dB)	200	115°C
350	11 mW (15 dB)	180	119°C

Table 2 shows that the TPA301 can be used to its full 350-mW rating without any heat sinking in still air up to 46°C.

# TPA301 350-mW LOW-VOLTAGE AUDIO POWER AMPLIFIER

SLOS208B – JANUARY 1998 – REVISED OCTOBER 1998

## MECHANICAL INFORMATION

**D (R-PDSO-G\*\*)**

**PLASTIC SMALL-OUTLINE PACKAGE**

14 PIN SHOWN

- NOTES: A. All linear dimensions are in inches (millimeters).  
 B. This drawing is subject to change without notice.  
 C. Body dimensions do not include mold flash or protrusion, not to exceed 0.006 (0,15).  
 D. Falls within JEDEC MS-012

# TPA301 350-mW LOW-VOLTAGE AUDIO POWER AMPLIFIER

SLOS208B – JANUARY 1998 – REVISED OCTOBER 1998

## MECHANICAL INFORMATION

DGN (S-PDSO-G8)

PowerPAD™ PLASTIC SMALL-OUTLINE PACKAGE

4073271/A 01/98

- NOTES:
- All linear dimensions are in millimeters.
  - This drawing is subject to change without notice.
  - Body dimensions include mold flash or protrusions.
  - The package thermal performance may be enhanced by attaching an external heat sink to the thermal pad. This pad is electrically and thermally connected to the backside of the die and possibly selected leads. The dimension of the thermal pad is 1.40 mm (height as illustrated) × 1.80 (width as illustrated) mm (maximum). The pad is centered on the bottom of the package.
  - Falls within JEDEC MO-187

PowerPAD is a trademark of Texas Instruments Incorporated.

POST OFFICE BOX 655303 • DALLAS, TEXAS 75265

## IMPORTANT NOTICE

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgement, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

CERTAIN APPLICATIONS USING SEMICONDUCTOR PRODUCTS MAY INVOLVE POTENTIAL RISKS OF DEATH, PERSONAL INJURY, OR SEVERE PROPERTY OR ENVIRONMENTAL DAMAGE ("CRITICAL APPLICATIONS"). TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS. INCLUSION OF TI PRODUCTS IN SUCH APPLICATIONS IS UNDERSTOOD TO BE FULLY AT THE CUSTOMER'S RISK.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards must be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance or customer product design. TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used. TI's publication of information regarding any third party's products or services does not constitute TI's approval, warranty or endorsement thereof.
