

TPS2216

DUAL-SLOT PC CARD POWER-INTERFACE SWITCH FOR SERIAL PCMCIA CONTROLLERS

SLVS179 – DECEMBER 1998

- Fully Integrated xVCC and xVPP Switching
- xVPP Programmed Independent of xVCC
- 3.3-V, 5-V, and/or 12-V Power Distribution
- Low $r_{DS(on)}$ (60-m Ω xVCC Switch Typical)
- Short Circuit and Thermal Protection
- 150- μ A (maximum) Quiescent Current
- Standby Mode: 50-mA Current Limit (Typ)
- 12-V Supply Can Be Disabled
- 3.3-V Low-Voltage Mode
- Meets PC Card™ Standards
- TTL-Logic Compatible Inputs
- Available in 30-Pin SSOP (DB) and 32-Pin TSSOP (DAP) Packages
- Break-Before-Make Switching
- Internal Power-on Reset

description

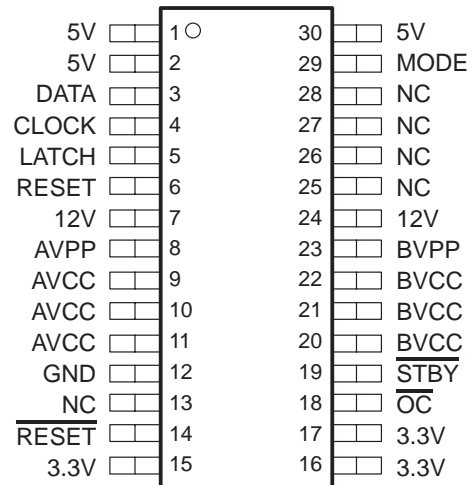

The TPS2216 PC Card power-interface switch provides an integrated power-management solution for two PC Cards. All of the discrete power MOSFETs, a logic section, current limiting, and thermal protection for PC Card control are combined on a single integrated circuit. This device allows the distribution of 3.3-V, 5-V, and/or 12-V power to the card. The current-limiting feature eliminates the need for fuses. Current-limit reporting can help the user isolate a system fault.

The TPS2216 features a 3.3-V low-voltage mode that allows for 3.3-V switching without the need for 5-V power. This feature facilitates low-power system designs such as sleep modes where only 3.3 V is available. The TPS2216 also has the ability to program the xVPP outputs independent of the xVCC outputs. A standby mode has been incorporated which changes all output current limits to 50 mA (typical).

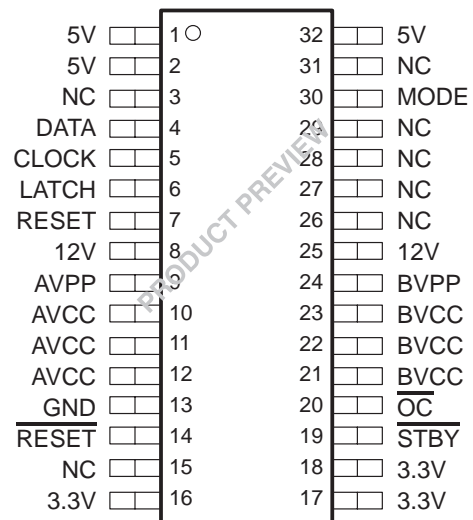

End-equipment applications for the TPS2216 include: notebook computers, desktop computers, personal digital assistants (PDAs), digital cameras, and bar-code scanners.

The TPS2216 is backward compatible with the TPS2202A and TPS2206.

AVAILABLE OPTIONS

T _J	PACKAGED DEVICES†	
	PLASTIC SMALL OUTLINE (DB)	PowerPAD PLASTIC SMALL OUTLINE™ (DAP)
0°C to 125°C	TPS2216IDB(R)	TPS2216IDAP(R)

† The DB and DAP packages are available in tubes and left-end taped and reeled. Add (R) suffix to device type [e.g., TPS2216IDB(R) for taped and reeled].

Terminal Functions

NAME	TERMINAL NO.		I/O	DESCRIPTION
	DB-30	DAP-32		
	3.3V	15, 16, 17		
5V	1, 2, 30	1, 2, 32	I	5-V input for card power and/or chip power
12V	7, 24	8, 25	I	12-V V _{pp} input card power
AVCC	9, 10, 11	10, 11, 12	O	VCC output: 3.3-V, 5-V, GND or high impedance to card
AVPP	8	9	O	VPP output: 3.3-V, 5-V, 12-V, GND or high impedance to card
BVCC	20, 21, 22	21, 22, 23	O	VCC output: 3.3-V, 5-V, GND or high impedance to card
BVPP	23	24	O	VPP output: 3.3-V, 5-V, 12-V, GND or high impedance to card
GND	12	13		Ground
MODE	29	30	I	TPS2206 operation when floating or pulled low; must be pulled high externally for TPS2216 operation. MODE is internally pulled low with a 150-kΩ pull down resistor.
$\overline{\text{OC}}$	18	20	O	Logic-level output that goes low when an overcurrent or overtemperature condition exists.
RESET	6	7	I	Logic-level reset input active high. Do not connect if $\overline{\text{RESET}}$ pin is used. RESET is internally pulled low with a 150-kΩ pull down resistor.
$\overline{\text{RESET}}$	14	14	I	Logic-level reset input active low. Do not connect if RESET pin is used. The pin is internally pulled high with a 150-kΩ pull up resistor.
$\overline{\text{STBY}}$	19	19	I	Logic-level active low input sets the TPS2216 to standby mode and sets all current limits to 50 mA. The pin is internally pulled high with a 150-kΩ pull up resistor.
CLOCK	4	5	I	Logic-level clock for serial data word
DATA	3	4	I	Logic-level serial data word
LATCH	5	6	I	Logic-level latch for serial data word
NC	13, 25, 26, 27, 28	3, 15, 26, 27, 28, 29, 31		No internal connection

SLVS179 – DECEMBER 1998

absolute maximum ratings over operating virtual free-air temperature (unless otherwise noted)†

Input voltage range for card power: $V_{I(3.3V)}$	-0.3 V to 6 V
$V_{I(5V)}$	-0.3 V to 6 V
$V_{I(12V)}$	-0.3 V to 14 V
Logic input voltage	-0.3 V to 6 V
Output voltage range: $V_{O(xVCC)}$	-0.3 V to 6 V
$V_{O(xVPP)}$	-0.3 V to 14 V
Continuous total power dissipation	See Dissipation Rating Table
Output current: $I_{O(xVCC)}$	Internally limited
$I_{O(xVPP)}$	Internally limited
Operating virtual junction temperature range, T_J	0°C to 125°C
Storage temperature range, T_{stg}	-55°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

† Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

APPLICATION INFORMATION

overview

PC Cards were initially introduced as a means to add EEPROM (flash memory) to portable computers with limited on board memory. The idea of add-in cards quickly took hold; modems, wireless LANs, Global Positioning Satellite System (GPS), multimedia, and hard-disk versions were soon available. As the number of PC Card applications grew, the engineering community quickly recognized the need for a standard to ensure compatibility across platforms. To this end, the PCMCIA (Personal Computer Memory Card International Association) was established, comprising members from leading computer, software, PC Card, and semiconductor manufacturers. One key goal was to realize the plug-and-play concept. Cards and hosts from different vendors should be compatible or able to communicate with one another transparently.

PC Card power specification

System compatibility also means power compatibility. The most current set of specifications (PC Card Standard) set forth by the PCMCIA committee states that power is to be transferred between the host and the card through eight of the 68 terminals of the PC Card connector. This power interface consists of two V_{CC}, two V_{pp}, and four ground terminals. Multiple V_{CC} and ground terminals minimize connector terminal and line resistance. The two V_{pp} terminals were originally specified as separate signals, but are commonly tied together in the host to form a single node to minimize voltage losses. Card primary power is supplied through the V_{CC} terminals; flash-memory programming and erase voltage is supplied through the V_{pp} terminals.

APPLICATION INFORMATION

designing for voltage regulation

The current PCMCIA specification for output voltage regulation, $V_{O(\text{reg})}$, of the 5-V output is 5% (250 mV). In a typical PC power-system design, the power supply has an output-voltage regulation, $V_{PS(\text{reg})}$, of 2% (100 mV). Also, a voltage drop from the power supply to the PC Card will result from resistive losses, V_{PCB} , in the PCB traces and the PCMCIA connector. A typical design would limit the total of these resistive losses to less than 1% (50 mV) of the output voltage. Therefore, the allowable voltage drop, V_{DS} , for the TPS2216 would be the PCMCIA voltage regulation less the power supply regulation and less the PCB and connector resistive drops:

$$V_{DS} = V_{O(\text{reg})} - V_{PS(\text{reg})} - V_{PCB}$$

Typically, this would leave 100 mV for the allowable voltage drop across the 5-V switch. The specification for output voltage regulation of the 3.3-V output is 300 mV; so, using the same equation by deducting the voltage drop percentages (2%) for power-supply regulation and PCB resistive loss (1%), the allowable voltage drop for the 3.3-V switch is 200 mV. The voltage drop is the output current multiplied by the switch resistance of the TPS2216. Therefore, the maximum output current, $I_{O \text{ max}}$, that can be delivered to the PC Card in regulation is the allowable voltage drop across the TPS2216, divided by the output-switch resistance.

$$I_{O \text{ max}} = \frac{V_{DS}}{r_{DS(\text{on})}}$$

The xVCC outputs can deliver 1 A continuous at 5 V and 3.3 V within regulation over the operating temperature range. The xVPP outputs of the TPS2216 can deliver 200 mA continuously.

overcurrent and overtemperature protection

PC Cards are inherently subject to damage that can result from mishandling. Host systems require protection against short-circuited cards that could lead to power-supply or PCB trace damage. Even systems robust enough to withstand a short circuit would still undergo rapid battery discharge into the damaged PC Card, resulting in the rather sudden and unacceptable loss of system power. Most hosts include fuses for protection. However, the reliability of fused systems is poor, as blown fuses require troubleshooting and repair, usually by the manufacturer.

The TPS2216 takes a two-pronged approach to overcurrent protection, which is designed to activate if an output is shorted or when an overcurrent condition is present when switches are powered up. First, instead of fuses, sense FETs monitor each of the xVCC and xVPP power outputs. Unlike sense resistors or polyfuses, these FETs do not add to the series resistance of the switch; therefore voltage and power losses are reduced. Overcurrent sensing is applied to each output separately. Excessive current generates an error signal that limits the output current of only the affected output, preventing damage to the host. Each xVCC output overcurrent limits from 1 A to 2.2 A, typically around 1.6 A; the xVPP outputs limit from 250 mA to 500 mA, typically around 375 mA.

Second, when an overcurrent condition is detected, the TPS2216 asserts an active low \overline{OC} signal that can be monitored by the microprocessor or controller to initiate diagnostics and/or send the user a warning message. In the event that an overcurrent condition persists, causing the IC to exceed its maximum junction temperature, thermal-protection circuitry activates. This shuts down all power outputs until the device cools to within a safe operating region, which is ensured by a thermal shutdown hysteresis.

TPS2216

DUAL-SLOT PC CARD POWER-INTERFACE SWITCH FOR SERIAL PCMCIA CONTROLLERS

SLVS179 – DECEMBER 1998

APPLICATION INFORMATION

12-V supply not required

Many PC Card switches use the externally supplied 12 V to power gate drive and other chip functions, which requires that power be present at all times. The TPS2216 offers considerable power savings by using an internal charge pump to generate the required higher gate drive voltages from the 5 V or 3.3 V power supplies. Therefore, the external 12 V supply can be disabled except when needed for flash-memory functions, thereby extending battery lifetime. Additional power savings are realized by the TPS2216 during shutdown mode, in which quiescent current drops to a maximum of 1 μ A.

3.3-V low-voltage mode

The TPS2216 will operate in 3.3-V low-voltage mode when 3.3 V is the only available input voltage ($V_{I(5V)} = 0$, $V_{I(12V)} = 0$). This feature allows host and PC Cards to be operated in low-power 3.3-V-only modes such as sleep modes. Note that in this operation mode, the TPS2216 will derive its bias current from the 3.3-V input pin and can only provide 3.3 V to the outputs.

voltage transitioning requirement

PC Cards are migrating from 5 V to 3.3 V to minimize power consumption, optimize board space, and increase logic speeds. The TPS2216 meets all combinations of power delivery as currently defined in the PCMCIA standard. The latest protocol accommodates mixed 3.3-V/5-V systems by first powering the card with 5 V, then polling it to determine its 3.3-V compatibility. The PCMCIA specification requires that the capacitors on 3.3-V-compatible cards be discharged to below 0.8 V before applying 3.3-V power. This action ensures that sensitive 3.3-V circuitry is not subjected to any residual 5-V charge and functions as a power reset. PC Card specification requires that V_{CC} be discharged within 100 ms. PC Card resistance can not be relied on to provide a discharge path for voltages stored on PC Card capacitance because of possible high-impedance isolation by power-management schemes. The TPS2216 includes discharge transistors on all xVCC and xVPP outputs to meet the specification requirement.

shutdown mode

In the shutdown mode, which can be controlled by bit D8 of the input serial DATA word, each of the xVCC and xVPP outputs is forced to a high-impedance state. In this mode, the chip quiescent current is limited to 1 μ A or less to conserve battery power.

standby mode

The TPS2216 can be put in standby mode by pulling \overline{STBY} low to conserve power during low-power operation. In this mode, all of the power outputs (xVCC and xVPP) will have a nominal current limit of 50 mA. \overline{STBY} has an internal 150-k Ω pull-up resistor. The output-switch status of the device must be set, allowing the output capacitors to charge, prior to enabling the standby mode. Changing the setting of the output switches with the device in standby mode may cause an overcurrent response to be generated.

mode

The mode pin programs the switches in either TPS2216 or TPS2206 mode. An internal 150-k Ω pull-down resistor is connected to the pin. Floating or pulling the mode pin low sets the switches in TPS2206 mode; pulling the mode pin high sets the switches in TPS2216 mode. In TPS2206 mode, xVPP outputs are dependent on xVCC outputs. In TPS2216 mode, xVPP is programmed independent of xVCC. Refer to TPS2216 control-logic tables for more information.

POST OFFICE BOX 655303 • DALLAS, TEXAS 75265

APPLICATION INFORMATION

power supply considerations

The TPS2216 has multiple pins for each of its 3.3-V and 5-V power inputs and for the switched xVCC outputs. Any individual pin can conduct the rated input or output current. Unless all pins are connected in parallel, the series resistance is higher than that specified, resulting in increased voltage drops and less power. It is recommended that all input and output power pins be paralleled for optimum operation. Because the two 12-V pins are not internally connected, they must be tied together externally.

To increase the noise immunity of the TPS2216, the power-supply inputs should be bypassed with a 1- μ F electrolytic or tantalum capacitor paralleled by a 0.047- μ F to 0.1- μ F ceramic capacitor. It is strongly recommended that the switched outputs be bypassed with a 0.1- μ F (or larger) ceramic capacitor; doing so improves the immunity of the TPS2216 to electrostatic discharge (ESD). Care should be taken to minimize the inductance of PCB traces between the TPS2216 and the load. High switching currents can produce large negative voltage transients, which forward biases substrate diodes, resulting in unpredictable performance. Similarly, no pin should be taken, or allowed to fall, below -0.3 V.

RESET and $\overline{\text{RESET}}$ inputs

To ensure that cards are in a known state after power brownouts or system initialization, the PC Cards should be reset at the same time as the host by applying low impedance paths from xVCC and xVPP terminals to ground. A low-impedance output state allows discharging of residual voltage remaining on PC Card filter capacitance, permitting the system (host and PC Cards) to be powered-up concurrently. The active-high RESET or active low $\overline{\text{RESET}}$ input will close internal switches S1, S4, S7, and S11 with all other switches left open. The TPS2216 remains in the low-impedance output state until the signal is deasserted and further data is clocked in and latched. The input serial data can not be latched during Reset mode. RESET and $\overline{\text{RESET}}$ are provided for direct compatibility with systems that use either an active-low or active-high reset voltage supervisor. The RESET pin has an internal 150-k Ω pull down resistor and the $\overline{\text{RESET}}$ pin has an internal 150-k Ω pull up resistor. The device will be reset automatically when powered up.

calculating junction temperature

The switch resistance, $r_{\text{DS(on)}}$, is dependent on the junction temperature, T_J , of the die. The junction temperature is dependent on both $r_{\text{DS(on)}}$ and the current through the switch. To calculate T_J , first find $r_{\text{DS(on)}}$ from Figures 23 through 26, using an initial temperature estimate about 50°C above ambient. Then calculate the power dissipation for each switch, using the formula:

$$P_D = r_{\text{DS(on)}} \times I^2$$

Next, sum the power dissipation and calculate the junction temperature:

$$T_J = \left(\sum P_D \times R_{\theta\text{JA}} \right) + T_A$$

Where:

$R_{\theta\text{JA}}$ is the inverse of the derating factor given in the dissipation rating table.

Compare the calculated junction temperature with the initial temperature estimate. If the temperatures are not within a few degrees of each other, recalculate using the calculated temperature as the initial estimate.

logic inputs and outputs

The serial interface consists of DATA, CLOCK, and LATCH leads. The data is clocked in on the positive edge of the clock (see Figures 2 and 3). The 11-bit (D0–D10) serial data word is loaded during the positive edge of the latch signal. The positive edge of the latch signal should occur before the next positive edge of the clock occurs.

TPS2216 DUAL-SLOT PC CARD POWER-INTERFACE SWITCH FOR SERIAL PCMCIA CONTROLLERS

SLVS179 – DECEMBER 1998

APPLICATION INFORMATION

ESD protections (see Figure 34)

All TPS2216 inputs and outputs incorporate ESD-protection circuitry designed to withstand a 2-kV human-body-model discharge as defined in MIL-STD-883C, Method 3015. The xVCC and xVPP outputs can be exposed to potentially higher discharges from the external environment through the PC Card connector. Bypassing the outputs with 0.1- μ F capacitors protects the devices from discharges up to 10 kV.

† Maximum recommended output capacitance for xVCC is 220 μ F and for xVPP is 10 μ F without \overline{OC} glitch when switches are powered on.

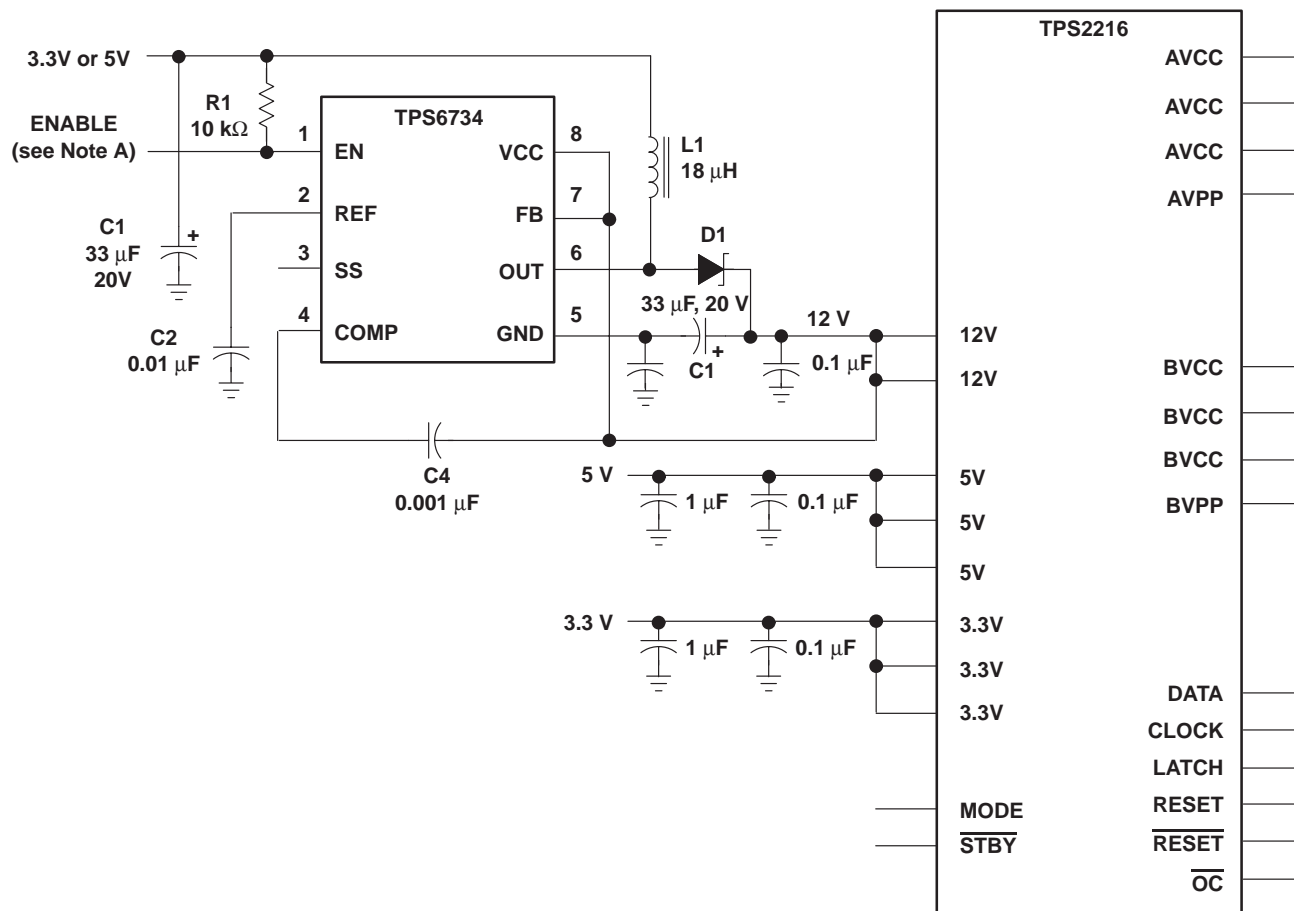

Figure 34. Detailed Interconnections and Capacitor Recommendations

APPLICATION INFORMATION

12-V flash memory supply

The TPS6734 is a fixed 12-V output boost converter capable of delivering 120 mA from inputs as low as 2.7 V. The device is pin-for-pin compatible with the MAX734 regulator and offers the following advantages: lower supply current, wider operating input-voltage range, and higher output currents. As shown in Figure 35, the only external components required are: an inductor, a Schottky rectifier, an output filter capacitor, an input filter capacitor, and a small capacitor for loop compensation. The entire converter occupies less than 0.7 in² of PCB space when implemented with surface-mount components. An enable input is provided to shut the converter down and reduce the supply current to 3 μ A when 12 V is not needed.

The TPS6734 is a 170-kHz current-mode PWM (pulse-width modulation) controller with an n-channel MOSFET power switch. Gate drive for the switch is derived from the 12-V output after start-up to minimize the die area needed to realize the 0.7- Ω MOSFET and improve efficiency at input voltages below 5 V. Soft start is accomplished with the addition of one small capacitor. A 1.22-V reference (pin 2) is brought out for external use. For additional information, see the TPS6734 data sheet (SLVS127).

NOTE A: The enable terminal can be tied to a general purpose I/O terminal on the PCMCIA controller or tied high.
